(54) Title: RECIPROCAL SUBTRACTION DIFFERENTIAL DISPLAY

(57) Abstract

This invention provides a method for identifying differentially expressed nucleic acids between two samples, comprising: a) selecting a first and second nucleic acid sample; b) producing libraries for the first and second nucleic acid sample; c) performing reciprocal subtraction between the libraries to produce two subtracted libraries; d) amplifying the two subtracted libraries; and e) comparing the two amplified subtracted libraries to identify differentially expressed nucleic acids. Also, this invention provides the above–described method, wherein the 3' primer used in the PCR amplification is an oligo dT 3' primer. This invention also provides the above–described methods, wherein the comparing of step e comprises using a gel to separate the nucleic acids from both of the libraries. This invention provides the isolated nucleic acid identified by the above–described methods, wherein the nucleic was not previously known to be differentially expressed between the two samples.

RECIPROCAL SUBTRACTION DIFFERENTIAL DISPLAY

5   This application is a continuation-in-part of U.S. Serial
No. 09/197,889, filed November 23, 1998, which is a
continuation-in-part of U.S. Serial Application No.
09/185,115, filed November 3, 1998 which is a
continuation-in-part of U.S. Serial Application No.
10   09/032,684, filed February 27, 1998. The content of the
above identified applications are hereby incorporated
into this application by reference.

Throughout this application, various references are
15   referred to within parentheses. Disclosures of these
publications in their entireties are hereby incorporated
by reference into this application to more fully describe
the state of the art to which this invention pertains.

20   **Background of the Invention**
Changes in gene expression are important determinants of
normal cellular physiology, including cell cycle
regulation, differentiation and development, and they
directly contribute to abnormal cellular physiology,
25   including developmental anomalies, aberrant programs of
differentiation and cancer (1-4). In these contexts,
the identification, cloning and characterization of
differentially expressed genes will provide relevant and
important insights into the molecular determinants of
30   processes such as growth, development, aging,
differentiation and cancer. A number of procedures can
be used to identify and clone differentially expressed
genes. These include, subtractive hybridization (5-10),
differential RNA display (DDRT-PCR) (3,4, 11,12), RNA
35   fingerprinting by arbitrarily primed PCR (RAP-PCR)
(13,14), representational difference analysis (RDA) (15),
serial analysis of gene expression (SAGE) (16,17),
electronic subtraction (18,19) and combinatorial gene
matrix analyses (20).

-2-

Since first introduced by Liang and Pardee (11), DDRT-PCR has gained wide popularity in analyzing and cloning differentially expressed genes. In DDRT-PCR, total RNAs or mRNAs from two or more cell types (or cells grown

5   under different conditions, cells representing different stages of development, cells treated with agents modifying cellular physiology, etc.) are reverse-transcribed with two-base-pair anchored oligo dT primers, which divide mRNA populations into 12 cDNA

10   subgroups. Then, each cDNA subgroup is amplified by PCR with one of 20 arbitrary 10-mer 5' primers and a 3' anchored primer and the PCR-amplified cDNA fragments are resolved in DNA sequencing gels. The combinations of primers are designed not only to yield a detectable size

15   and number of bands, but also to display nearly the complete repertoire of mRNA species.

DDRT-PCR is a powerful methodology in which a vast number of mRNA species (>20,000, if no redundancy occurs) can be

20   analyzed with only a small quantity of RNA (about 5 μg) (11). DDRT-PCR is often the method of choice when the RNA source is limiting, such as tissue biopsies. A direct advantage of DDRT-PCR is the ability to identify and isolate both up- and down-regulated differentially

25   expressed genes in the same reaction. Furthermore, the DDRT-PCR technique permits the display of multiple samples in the same gel, which is useful in defining specific diagnostic alterations in RNA species and for temporally analyzing gene expression changes. However,

30   the DDRT-PCR technique is not problem free. Difficulties encountered when using standard DDRT-PCR include, a high incidence of false positives and redundant gene identification, poor reproducibility, biased gene display and lack of functional information about the cloned cDNA.

35   Furthermore, poor separation can mask differentially expressed genes of low abundance under the intense signals generated by highly expressed genes. The

-3-

generation of false positives and redundancy can be highly problematic, resulting in an inordinate expenditure of resources to confirm appropriate differential expression and uniqueness of the isolated
5   cDNAs. The cDNAs must be isolated from the gels in pure form (contamination of bands with multiple sequences complicates clone identification), reamplified, placed in an appropriate cloning vector, analyzed for authentic differential expression and finally sequenced. These
10   limitations of the standard DDRT-PCR approaches emphasize the need for improvements in this procedure to more efficiently and selectively identify differentially expressed genes.

15   A number of modifications and improvements of the DDRT-PCR approach have been described (21-23). Single anchor or degenerate two-base anchor oligo dT primers can be used to streamline the massive numbers of reverse transcription and PCR reactions required for validation
20   of cDNAs as well as to reduce false positives (24,25). Reproducibility can be improved by lengthening the arbitrary 5' primers to accommodate a convenient restriction site followed by two cycles of PCR with successive low- and high-stringency annealing
25   temperatures (25,26). DDRT-PCR with inosine-containing 5' arbitrary primers can also increase reproducibility of this approach (27). However, since these modifications have only been analyzed using a subset of primers, further studies are necessary to validate these
30   modifications of DDRT-PCR with additional primers and in several model systems.

In addition to genomic DNA contamination, mispriming, PCR artifacts, the high incidence of false positives and
35   redundancy is also ascribed to poor separation between bands and the complexity of the templates amplified (28). Furthermore, poor separation can mask differentially

-4-

expressed genes of low abundance under the intense
signals generated by highly expressed genes.   By
enriching for unique cDNAs and removing common ones, it
should in principle be possible to enrich for low
5   abundant gene products and significantly decrease the
complexity of amplified sequences.   In addition, the
sequence bias of DDRT-PCR should also be reduced by
decreasing template complexity. These assumptions serve
as the basis for the development of reciprocal
10   subtraction differential RNA display (RSDD).

Subtractive hybridization, in which hybridization between
tester and driver is followed by selective removal of
common gene products, enriches for unique gene products
15   in the tester cDNA population and reduces the abundance
of common cDNAs (9). A subtracted cDNA library can be
analyzed to identify and clone differentially expressed
genes by randomly picking colonies or by differential
screening (29-31).   Although subtractive hybridization
20   has been successfully used to clone a number of
differentially expressed genes (5-7,10), this approach is
both labor-intensive and does not result in isolation of
the full spectrum of genes displaying altered expression
(9,18).

25

In principle, DDRT-PCR performed with subtracted RNA or
cDNA samples represents a powerful strategy to clone up
and down-regulated gene products. This approach should
result in the enrichment of unique sequences and a
30   reduction or elimination of common sequences.   This
scheme should also result in a consistent reduction in
band complexity on a display gel, thereby permitting a
clearer separation of cDNAs resulting in fewer false
positive reactions. Additionally, it should be possible
35   to use fewer primer sets for reverse transcription and
PCR reactions to analyze the complete spectrum of
differentially expressed genes. Of particular importance

-5-

for gene identification and isolation, rare gene products
that are masked by strong common gene products should be
displayed by using subtraction hybridization in
combination with DDRT-PCR. In addition, the DDRT-PCR
approach with subtractive libraries could also prove
valuable for efficiently screening subtracted cDNA
libraries for differentially expressed genes. However,
even though subtraction hybridization plus DDRT-PCR
appears attractive for the reasons indicated above, a
previous attempt to use this approach has proven of only
marginal success in consistently reducing the complexity
of the signals generated, compared with the standard
DDRT-PCR scheme (32).

We presently describe a reciprocal subtraction
differential RNA display (RSDD) approach that efficiently
and consistently reduces the complexity of DDRT-PCR and
results in the identification and cloning of genes
displaying anticipated differential expression.

-6-

Summary of the Invention

This invention provides a method for identifying differentially expressed nucleic acids between two samples, comprising: (a) selecting a first and second nucleic acid sample, wherein the nucleic acid samples contain a repertoire of nucleic acids; (b) performing reciprocal subtraction between the nucleic acid samples to produce two subtracted nucleic acid samples; (c) amplifying the two subtracted nucleic acid samples; and (d) comparing the two subtracted nucleic acid samples to identify differentially expressed nucleic acids.

This invention also provides a method for identifying differentially expressed nucleic acids between two samples, comprising: (a) selecting a first and second nucleic acid sample, wherein the nucleic acid samples contain a repertoire of nucleic acids; (b) amplifying the two nucleic acid samples; (c) performing reciprocal subtraction between the amplified nucleic acid samples to produce two subtracted nucleic acid samples; and (d) comparing the two subtracted nucleic acid samples to identify differentially expressed nucleic acids.

This invention further provides the above-described methods, wherein the first and second nucleic acid samples are obtained from cells in different developmental stages.

This invention further provides the above-described methods, wherein the first and second nucleic acid samples are obtained from cells from different tissue types.

Also, this invention provides the above-described methods, wherein the 3' primer used in the PCR amplification is an oligo dT 3' primer.

-7-

In addition, this invention provides the above-described methods, wherein the 3' primer used in the PCR amplification is a single anchor oligo dT 3' primer.

This invention also provides the above-described methods, wherein the comparing of step (e) comprises using a gel to separate the nucleic acids from both of the libraries.

This invention provides the isolated nucleic acid identified by the the above-described methods, wherein the nucleic acid was not previously known to be differentially expressed between the two samples.

<u>Figure 32</u>

Schematic outline of the reciprocal differential RNA display (RSDD) protocol. This scheme incorporates three steps, reciprocal subtraction of cDNA libraries, differential display of *in vivo* excised cDNAs and expression analysis by reverse Northern and standard Northern blotting. For the present application of RSDD, reciprocal subtraction hybridization was performed using libraries constructed from E11 and E11-NMT cells, i.e., E11 minus E11-NMT and E11-NMT minus E11. Differentially expressed cDNAs identified on gels using differential RNA were isolated, reamplified and analyzed for expression by reverse Northern blotting. To confirm differential expression cDNAs were analyzed using Northern blotting.

Detailed Description of the Invention

This invention provides a method for identifying differentially expressed nucleic acids between two samples, comprising: (a) selecting a first and second nucleic acid sample, wherein the nucleic acid samples contain a repertoire of nucleic acids; (b) performing reciprocal subtraction between the nucleic acid samples to produce two subtracted nucleic acid samples; (c) amplifying the two subtracted nucleic acid samples; and (d) comparing the two subtracted nucleic acid samples to identify differentially expressed nucleic acids.

In an embodiment, the nucleic acid samples are mRNA or derived from mRNA. In another embodiment, the nucleic acid samples are total RNA. In another embodiment, the nucleic acid samples are cDNA. In another embodiment, the nucleic acid samples are a nucleic acid library.

In an embodiment, differentially expressed nucleic acids are expressed at different levels. In a further embodiment, one of the nucleic acids is not expressed. In a different embodiment, one of the nucleic acids is expressed in truncated form.

As used herein, reciprocal subtraction includes using nucleic acid sample A to subtract common nucleic acids from nucleic acid sample B (based on hybridization) and also using nucleic acid sample B to subtract common nucleic acids from nucleic sample A. In an embodiment, the complement of nucleic acid sample A is used to subtract nucleic acids from nucleic acid sample B and the complement of nucleic acid sample B is used to subtract nucleic acids from nucleic acid sample A. In a further embodiment, the RNA of nucleic acid sample A is used to subtract nucleic acids from nucleic acid sample B and the RNA of nucleic acid sample B is used to subtract nucleic acids from nucleic acid sample A. In yet another

-15-

embodiment, the cDNA of nucleic acid sample A is used to subtract nucleic acids from nucleic acid sample B and the cDNA of nucleic acid sample B is used to subtract nucleic acids from nucleic acid sample A.

As used herein, methods of amplification include PCR and rolling circle replication.

A basic description of nucleic acid amplification is described in Mullis, U.S. Patent No. 4,683,202, which is incorporated herein by reference. The amplification reaction uses a template nucleic acid contained in a sample, two primer sequences and inducing agents. The extension product of one primer when hybridized to the second primer becomes a template for the production of a complementary extension product and vice versa, and the process is repeated as often as is necessary to produce a detectable amount of the sequence.

The inducing agent may be any compound or system which will function to accomplish the synthesis of primer extension products, including enzymes. Suitable enzymes for this purpose include, for example, *E.coli* DNA polymerase I, thermostable *Taq* DNA polymerase, Klenow fragment of *E.coli* DNA polymerase I, T4 DNA polymerase, other available DNA polymerases, reverse transcriptase and other enzymes which will facilitate combination of the nucleotides in the proper manner to form amplification products. The oligonucleotide primers can be synthesized by automated instruments sold by a variety of manufacturers or can be commercially prepared based upon the nucleic acid sequence of this invention.

This invention also provides a method for identifying differentially expressed nucleic acids between two samples, comprising: a) selecting a first and second nucleic acid sample; b) producing libraries for the first

-16-

and second nucleic acid sample; c) amplifying the two
libraries; d) performing reciprocal subtraction between
the amplified libraries to produce two subtracted
libraries; and e) comparing the two subtracted libraries
5   to identify differentially expressed nucleic acids.

This invention also provides a method for identifying
differentially expressed nucleic acids between two
samples, comprising: (a) selecting a first and second
10   nucleic acid sample, wherein the nucleic acid samples
contain a repertoire of nucleic acids; (b) amplifying the
two nucleic acid samples; (c) performing reciprocal
subtraction between the amplified nucleic acid samples to
produce two subtracted nucleic acid samples; and (d)
15   comparing the two subtracted nucleic acid samples to
identify differentially expressed nucleic acids.

This invention also provides the above-described methods,
wherein the two subtracted nucleic acid samples from step
20   c are amplified prior to the comparing of step d.

This invention also provides the above-described methods,
wherein the each of the nucleic acid samples comprises a
library of nucleic acids.
25

This invention also provides the above-described methods,
wherein the nucleic acid samples are obtained from total
cellular RNA purified by hybridization with oligo (dT).

30   This invention also provides the above-described methods,
wherein the nucleic acid samples are obtained from total
RNA from E11 and E11-NMT cells.

E11 is an adenovirus-transformed rat embryo cell line
35   that acquires an aggressive oncogenic progression
phenotype when injected into athymic nude mice and
reisolated in cell culture (E11-NMT).

-17-

This invention further provides the above-described methods, wherein the first and second nucleic acid samples are obtained from cells in different developmental stages.

This invention further provides the above-described methods, wherein the first and second nucleic acid samples are obtained from cells from different tissue types.

This invention further provides the above-described methods, wherein the first and second nucleic acid samples are obtained from cells that differ in their exposure to external factors or in their gene expression.

In an embodiment, cells that differ in their exposure to external factors or in their gene expression includes any cells that may have different levels of gene expression, wherein some genes may not be expressed at all. In another embodiment, cells that differ in their exposure to external factors or in their gene expression includes any cells that are likely to have different levels of gene expression, wherein some genes may not be expressed at all. In still another embodiment, cells that differ in their exposure to external factors or in their gene expression includes any cell that has a phenotypically recognizable difference.

A short list of examples of cells that differ in their exposure to external factors or in their gene expression includes: cancerous versus normal cells, advanced cancer progression cells versus ealier cancer stage cells, diseased cells versus nondiseased cells, infected cells versus noninfected cells, later developmental stage cells versus earlier developmental stage cells, cells after DNA damage versus cells before DNA damage, senescent cells versus younger cells, cells induced by growth factors

-18-

versus cells not induced by growth factors, cells in the process of neurodegeneration versus normal cells, and cells exposed to a chemotherapeutic agent versus normal cells.

5

As used herein, different tissues types include but are not limited to tissues containing: cells grown under or exposed to different conditions, cells in different stages of development, cells treated with agents 10 modifying cellular physiology, and cells having different functions.

In an embodiment, cells at different stages of development are cells taken or analyzed at times 15 differing by one or more hours in the development of the cell or organism.

Further, this invention provides the above-described methods, wherein the amplifying of step (d) comprises PCR 20 amplification.

Also, this invention provides the above-described methods, wherein the 3' primer used in the PCR amplification is an oligo dT 3' primer. A few examples 25 of oligo dT primers are T_{13}, $T_{13}A$, and $T_{13}GA$.

In addition, this invention provides the above-described methods, wherein the 3' primer used in the PCR amplification is a single anchor oligo dT 3' primer. 30 Olgio dT 3' primers include $T_{13}A$, $T_{13}C$, and $T_{13}G$.

This invention provides the above-described methods, wherein the PCR amplification uses a set of random primers.

35

This invention provides the above-described methods, wherein the 5' primer is an arbitrary primer.

-19-

This invention also provides the above-described methods, wherein the comparing of step (e) comprises using a gel to separate the nucleic acids from both of the substracted libraries.

In an embodiment, the gel is a polyacrylamide gel. In another embodiment, the gel is an agarose gel.

This invention further provides the above-described methods, further comprising PCR amplifying the first and second nucleic acid samples.

This invention also provides the above-described methods, further comprising reamplifying differentially expressed bands.

This invention also provides the above-described methods, further comprising reamplifying differentially expressed nucleic acid.

In one method of reamplifying differentially expressed bands, differentially amplified bands from plasmids of each subtracted library were marked with an 18G needle through the film and cut out with a razor. The cut out differentially expressed bands can be reamplified (i.e. by PCR) and examined by reverse Northern and Northern blot analyses.

In addition, this invention provides the above-described methods, wherein the comparing of step (e) comprises comparing the band intensities of the two amplified differentially expressed nucleic acids.

In addition, this invention provides the above-described methods, wherein the nucleic acid samples are mRNA or cDNA derived from mRNA.

-20-

In addition, this invention provides the above-described methods, wherein the comparing of step (e) comprises comparing the quantities of the two amplified differentially expressed nucleic acids.

This invention further provides the above-described methods, wherein the differences in band intensity between the two subtracted libraries are electronically quantified.

This invention further provides the above-described methods, wherein the differences in the quantities of nucleic acid between the two subtracted libraries are electronically quantified.

In one embodiment, electronic quantification involves using a scanner to detect the bands. In a further embodiment, computer software, such as Corel Draw, can be used to determine the pixel intensity of the scanned image, thereby quantifying the band intensity.

Also, this invention provides the above-described methods, wherein the libraries of step (b) are constructed with λ-ZAP cDNA library kits. One skilled in the art would recognize that any cDNA library would be suitable.

This invention provides the isolated nucleic acid identified by the the above-described methods, wherein the nucleic acid was not previously known.

This invention also provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PSGen 12 (AI 144569).

In addition, this invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid

is the nucleic acid designated PSGen 13 (Accession No. AI 144570).

This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PSGen 23.

This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PSGen 24.

This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PSGen 25.

This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PSGen 26 (Accession No. AI 144571).

This invention also provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PSGen 27 (Accession No. AI 144572).

This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PSGen 28 (AI 144573).

This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PSGen 29 (AI 144574).

This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PEGen 13 (AI 144564).

-22-

This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PEGen 14 (AI 144565).

5   This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PEGen 15.

This invention provides the above-described isolated
10   nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PEGen 24 (Accession No. AI 144566).

This invention provides the above-described isolated
15   nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PEGen 28 (AI 144567).

This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the
20   nucleic acid designated PEGen 32 (AI 144568).

This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PEGen 42.

25
This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PEGen 43.

30   This invention provides the above-described isolated nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PEGen 44.

This invention provides the above-described isolated
35   nucleic acid, wherein the isolated nucleic acid is the nucleic acid designated PEGen 48.

-23-

This invention further provides a previously unknown
isolated nucleic acid molecule identified by the above-
described methods which comprises (a) one of the nucleic
acid sequences as set forth in Figure 35; (b) a sequence
5   being degenerated to a sequence of (a) as a result of the
genetic code; (c) a sequence encoding one of the amino
acid sequences as set forth in Figure 35.(d) a sequence
of at least 12 nucleotides capable of specifically
hybridizing to the sequence of (a), (b) or (c).
10

Finally, this invention provides a purified polypeptide
comprising one of the amino acid sequence as set forth in
Figure 35.

15   The sequences of the cDNA of PSGen 12, PSGen 13, PSGen
26, PSGen 27, PSGen 28, PSGen 29, PEGen 13, PEGen 14,
PEGen 24, PEGen 28, and PEGen 32 were submitted to
GenBank and assigned with accession numbers AI 144569, AI
144570, AI 144571, AI 144572, AI 144573, AI 144574, AI
20   144564, AI 144565, AI 144566, AI 144567 and AI 144568
respectively.

This invention will be better understood from the
Experimental Details which follow. However, one skilled
25   in the art will readily appreciate that the specific
methods and results discussed are merely illustrative of
the invention as described more fully in the claims which
follow thereafter.

30   **Experimental Details**
We presently describe a reciprocal subtraction
differential RNA display (RSDD) approach that efficiently
and consistently reduces the complexity of DDRT-PCR and
results in the identification and cloning of genes
35   displaying anticipated differential expression. Proof of
principle for the RSDD approach has come from its
application for the identification of genes

-24-

differentially expressed during cancer progression. RSDD has resulted in the identification and cloning of genes displaying elevated expression in progressed tumor cells (PEGen) and reduced expression in progressed tumor cells
5 (PSGen). The model used for RSDD was an adenovirus-transformed rat embryo cell line, E11, that acquires an aggressive oncogenic progression phenotype when injected into athymic nude mice and reisolated in cell culture (E11-NMT) (10,33,34). Injection of E11
10 cells into nude mice results in tumors in 100% of animals with a tumor latency time of approximately 35 to 40 days, whereas E11-NMT cells form tumors in 100% of nude mice with a tumor latency time of 15 to 20 days (10,34,35). Additionally, E11 cells form colonies in agar with an
15 efficiency of ~3%, whereas E11-NMT display an agar cloning efficiency of >30% (10,33,34). The increased tumorigenicity and enhanced anchorage independence phenotypes are key indicators of tumor progression in the E11/E11-NMT model system (10,33,34).

20

Differential RNA display was directly performed with reciprocally subtracted cDNA plasmid libraries (E11 minus E11-NMT and E11-NMT minus E11). Compared with the subtraction of PCR-amplified cDNA in Hakvoort et al., the
25 subtracted cDNA libraries used in this experiment are free from potential PCR artifacts and provide more stable and consistent sources for DDRT-PCR analyzes. In addition, three single anchored oligo dT 3' primers were used instead of two-base-anchored approach described by
30 Hakvoort et al (32). To further streamline the DDRT-PCR procedure, reamplified cDNAs identified using RSDD were analyzed using the reverse Northern blotting procedure (35,36). cDNAs displaying differential expression by reverse Northern blotting were subsequently confirmed for
35 true differential expression by Northern analysis. These modifications incorporated in the RSDD strategy result in an efficient approach for using subtractive hybridization

-25-

and DDRT-PCR for identifying differentially expressed
genes.

Methods

5   Total RNA from E11 and E11-NMT cells was isolated by the
guanidinium isothiocyanate/CsCl centrifugation procedure
and poly A⁺ RNA was purified with oligo(dT) cellulose
chromatography (5). Two λ-ZAP cDNA libraries from E11 and
E11-NMT mRNA's were constructed with λ-ZAP cDNA library
10   Kits (Stratagene) following the manufacturer's protocol.
Reciprocal subtraction between E11 and E11-NMT libraries
was performed and two subtracted cDNA libraries (E11
minus E11-NMT and E11-NMT minus E11) were constructed as
described previously. Bacterial plasmid libraries from
15   the subtracted λ-ZAP cDNA libraries were obtained by *in
vivo* excision following the manufacturer's protocol
(Stratagene) and the plasmids were isolated with Qiagen
columns (Qiagen Inc.).

20   The purified plasmids of reciprocally subtracted cDNA
libraries were directly subjected to differential display
as in Liang et. al. (38) with minor modifications. The
plasmids of reciprocally subtracted cDNA libraries were
PCR-amplified with the combination of three single-anchor
25   3' primers (T $_{13}$ A, T $_{13}$ C or T $_{13}$ G) and 18 arbitrary 5'
10-mer primers obtained from Operon Technology Inc.
(Alameda, CA. OPA 1-20 except OPA1 and 3). The 20 μl PCR
reaction consisted of 10 mM Tris-HCl pH 8.4, 50 mM KCl,
1.5 mM MgCl$_2$, 2 μM each dNTP, 0.2 μM 5' arbitrary primer,
30   1 μM 3' anchor primer, 50 ng of plasmid of a subtracted
library, 10 μCi α-^{35}S-dATP (3000 Ci/mmole from Amersham)
and 1 U of Taq DNA polymerase (Gibco BRL). The
parameters of PCR were 30 sec at 95 C, 40 cycle of 30 sec
at 95 C, 2 min. at 40 C and 30 sec at 72 C and additional
35   5 min. at 72 C. After the cycling, 10 μl of 95%
formamide, 0.05% bromophenol blue and 0.05% xylene cyanol
were added to each PCR reaction. The mixture was heated

-26-

at 95 °C for 2 min and separated in a 5% denaturing DNA
sequencing gel maintained at 50 °C. PCR reactions of
plasmids from each subtracted library in a primer set
were run side by side. Differentially amplified bands
from plasmids of each subtracted library were marked with
an 18G needle through the film and cut out with a razor.
The gel slice was put in 100 μl TE pH 8.0 and incubated
at 4 °C overnight. After the incubation, the mixture was
boiled for 5 min and microcentrifuged for two min. The
supernatant was collected and stored at -20 °C until
reamplification. The band extract was reamplified with
the same cycling parameters in a 50 μl reaction
consisting of 10 mM Tris-HCl pH 8.4, 50 mM KCl, 1.5 mM
MgCl$_2$, 20 μM each dNTP, 0.2 μM 5' arbitrary primer, 1 μM
3' anchor primer, 5 μl of band extract and 2.5 U of Taq
DNA polymerase (Gibco BRL).

Differential expression of the reamplified DNA fragment
was scrutinized by reverse Northern and Northern blot
analyses.   In   reverse   Northern   analysis,   after
confirmation in a 1% agarose gel, the reamplified DNA
fragment (10 μl of PCR reaction) was mixed with 90 μl TE
and spotted on a positively charged Nylon membrane
(Boehringer Mannheim) with a 96-well vacuum manifold.
The membrane was soaked with denaturing and neutralizing
solution   successively,   and   the   spotted   DNA   was
crosslinked to the membrane with a UV crosslinker
(Stratagene). ^{32}P-labeled first strand cDNA was prepared
by reverse transcription of total RNA. After heating at
70 °C for 10 min and quenching on ice for two min, 0.4 μM
each T $_{13}$ A, T $_{13}$ G and T $_{13}$ C and 10 μg total RNA mixture
was added with 50 mM Tris-HCl, pH 8.3, 75 mM KCl, 3 mM
MgCl2, 10 mM DTT, 0.5 mM dATP, 0.5 mM dGTP, 0.5 mM dTTP,
0.02 mM dCTP, 0.5 μl RNase inhibitor (Gibco BRL), 100 μCi
dCTP (3000 Ci/mmole from Amersham) and 200 U Superscript
RT II (Gibco BRL) in a final 25 μl reaction. The
reaction mixture was incubated at 42 °C for one hr and at

-27-

37 °C for 30 min after addition of 2 μl of RNase H (10U, Gibco BRL). The membrane was hybridized at 42 °C overnight in a 50% formamide hybridization solution. The hybridized membrane was washed at room temperature for 15 min with 2X SSC containing 0.1% SDS twice and at 55 °C for at least one hr with 0.1X SSC containing 0.1% SDS, successively. The membrane was probed with the ^{32}P-labeled cDNA of E11, stripped off and probed with ^{32}P-labeled cDNA of E11-NMT. The signal intensity of each spot was normalized against that of GAPDH and compared between E11 and E11-NMT. Reamplified DNA fragments displaying differential expression levels ≥1.8-fold higher between the two cell types were selected and analyzed by Northern blotting analysis.

In Northern blot analysis, 10 μg of total RNA from E11 and E11-NMT cells were run side-by-side in a 1% agarose gel with formaldehyde and transferred to a positively charged Nylon membrane. Reamplification reaction (5 μl) was ^{32}P-labeled with a multiprime labeling kit (Boehringer Mannheim) used to probe the membrane as described above. DNA fragments expressed differentially between E11 and E11-NMT in Northern blot analyses were cloned into the Eco RV site of the pZEro-2.1 cloning vector (Invitrogene) and sequenced. In order to confirm differential expression, the cloned cDNA fragment was released by Eco RI -Xho I, ^{32}P-labeled and used to probe Northern blots as described above. Samples of RNAs from various E11 and E11-NMT derivatives displaying either a progressed or suppressed progression phenotype, based on nude mice tumorigenesis and soft agar cloning assays were analyzed. These included E11, E11-NMT, CREF X E11-NMT F1 and F2 somatic cell hybrids (suppressed progression phenotype), CREF X E11-NMT R1 and R2 somatic cell hybrids (progression phenotype), E11 X E11-NMT A6 somatic cell hybrid (suppressed progression phenotype), E11 X E11-NMT A6TD tumor-derived somatic cell hybrid (progression

-28-

phenotype), E11 X E11-NMT 3b somatic cell hybrid (suppressed progression phenotype), E11 X E11-NMT 2a (progression phenotype), E11-NMT AZA B1 and C1 5-azacytidine treated E11-NMT clones (suppressed progression phenotype), E11-ras R12 clone containing the Ha-ras oncogene (progression phenotype) and E11-HPV E6/E7 clone containing the human papilloma virus-18 E6 and E7 gene region (progression phenotype). Differential expression of the PEGen and PSGen genes in the various cell types was confirmed using ^{32}P-labeled probes and Northern hybridization analysis. After reconfirmation of differential expression, the plasmids containing the differentially expressed DNA fragments were sequenced by the dideoxy sequencing procedure.

Results and Discussion

Subtraction hybridization provides a direct means of enriching for unique cDNA species and eliminating common sequences between complex genomes. DDRT-PCR is a proven methodology for the rapid identification and cloning of differentially expressed sequences between cell types (3,4,22). In principle, subtraction hybridization combined with DDRT-PCR should reduce band complexity which often obscures the identification of differentially expressed genes and generates false positive signals (23,28). This strategy, RSDD, has been used to analyze genes differentially expressed during transformation progression. The differential RNA display pattern of E11 and E11-NMT cells using standard differential RNA display DDRT-PCR) and RSDD is shown in Fig. 1 (Left Panel). As predicted, the differential RNA display pattern of RSDD was much less complex than that of DDRT-PCR. The majority of bands common to both cDNA samples were eliminated using RSDD. These experiments demonstrate that subtractive hybridization prior to differential RNA display is effective in simplifying display patterns

-29-

permits the efficient identification of differentially expressed cDNAs. Since RSDD significantly reduced the number of bands displayed, single anchor oligo dT primers, that can increase band numbers, were
5 successfully used in subsequent applications of the RSDD approach (Fig. 1; Right Panel). Using RSDD, 235 differentially displayed cDNAs in the E11/E11-NMT tumor progression model system were isolated.

10 Hakvoort et. al. (32) used a reciprocal subtraction approach to analyze gene expression changes resulting during liver regeneration following 70% hepatectomy, i.e., normal liver subtracted from partially hepatectomized regenerating liver and vice versa.
15 Although some bands displayed apparent enrichment, the complexity of the display pattern did not show appreciable simplification. These results are in stark contrast to RSDD, which results in a clear delineation and simplification of differentially expressed amplified
20 bands (Figs. 1). Although conceptually similar, RSDD is significantly more effective than the subtraction plus DDRT-PCR approach described by Hakvoort et al. (32). The improved efficiency of RSDD versus the Hakvoort et al. (32) approach can be attributed to several factors. The
25 approach of Hakvoort et al. (32) is based on the subtraction procedure described by Wang and Brown (38). This approach involves multiple rounds of PCR-amplification prior to each round of subtractive hybridization. In contrast, RSDD involves a single round
30 of reciprocal subtraction that does not involve PCR amplification (5,10). In this respect, the complicated display pattern observed by Hakvoort et al. (32) even after three or four rounds of subtraction might result from reduced subtraction efficiency, PCR artifacts or a
35 combination of these problems. Increasing the number of reactions by using two-base pair anchored oligo dT primers did not reduce the complexity of displayed bands

-30-

(32). In these contexts, a critical component for the successful use of RSDD involves the use of an appropriate subtraction hybridization protocol, that can efficiently reduce cDNA complexity and generate stable populations of cDNAs for analysis.

Previous studies demonstrate that different gene cloning strategies, including DDRT-PCR, subtraction hybridization and electronic display, identify dissimilar differentially expressed genes (18). These results suggest that a single approach for gene identification may not identify the complete spectrum of differentially expressed genes (18). Similarly, RSDD and DDRT-PCR do not resolve the same differentially expressed bands (Fig. 1). Unique bands identified in DDRT-PCR that were differentially expressed when analyzed by Northern blotting were not the same as those found using RSDD and vise versa. These results are not surprising, since, as indicated above, subtraction hybridization and differential RNA display identified distinct differentially expressed genes. Apparently, specific differentially expressed genes are lost during subtraction hybridization and differential RNA display of subtracted cDNAs. On the basis of these considerations, it will be essential to use multiple gene discovery approaches to identify and clone the complete spectrum of differentially expressed genes.

DDRT-PCR can generate large numbers of differentially displayed bands making subsequent analysis both labor intensive and a daunting challenge. In order to reduce these limitations of DDRT-PCR, RSDD has been used in combination with reverse Northern analyses of isolated cDNAs. Gel extracted cDNA fragments were reamplified, dot-blotted on Nylon membranes and successively probed with reverse transcribed ^{32}P-cDNA from E11 or E11-NMT RNAs (Fig. 2). Signals were detected in 181 reamplified bands

out of 235 (77%). This number is lower than that observed using DDRT-PCR (51 out of 54). However, this comparison may not be accurate since only four arbitrary primers were used for DDRT-PCR and fewer differentially expressed bands were detected and isolated. A possible reason for the high incidence of false positives in RSDD may be due to the existence of foreign plasmid-like DNA in the cDNAs and the inaccurate reading properties of DDRT-PCR.

-32-

Table 1.   Differentially Expressed cDNA Fragments
            Cloned by DDRT-PCR.

Nomenclature	Identity	Homology
PEGen 41	To be determined	
PEGen 42	Novel	Novel
PEGen 43	Novel	Novel
PEGen 44	Novel	Novel
PEGen 45	Hoxa11 locus antisense	mouse 90%
PEGen 46	Glutamyl t-RNA synthetase	human 59%
PEGen 48	Novel	Novel
PEGen 50	Novel	Novel
PSGen 1	Supervillin	*B. taurus 80%*
PSGen 2	HTLV-1 Tax interacting protein	human 91%
PSGen 4	Proteasome activator	Rat 100%
PSGen 27	Novel	

The signal intensities of the various cDNAs in reverse
Northern analysis were quantified and normalized against
that of GAPDH, which remained unchanged in E11 and
E11-NMT cells. The PEG-3 (PEGen-3) gene (10) was used as
an additional control, to verify increased expression in
E11-NMT versus E11 cells.   In the reverse Northern

-33-

analyses, PEGen-3 levels were 4-fold higher in E11-NMT than in E11 cells, which coincided with Northern blotting results, thereby demonstrating the concordance of reverse Northern and Northern assays. A ≥ 1.8-fold differential cut-off (after normalization for GAPDH expression) was used to identify and isolate cDNA bands displaying modified expression in E11 versus E11-NMT cells. This resulted in the identification of 7 cDNAs with higher expression in E11 versus E11-NMT cells and 65 cDNAs with elevated expression in E11-NMT versus E11 cells. These results suggest that tumor progression in E11-NMT cells correlates with the increased expression of a large number of genes, whereas only a smaller subset of genes display decreased expression.

A problem present in DDRT-PCR, that is reduced but still can occur in RSDD, is the isolation of multiple cDNA species from what appears to be a single amplified band. When this occurs, these multiple species can produce spurious results when analyzed by reverse Northern analyses. For example, if two distinct species are isolated, one displaying modified expression and a second not displaying modified expression, an accurate estimate of differential expression will not be obtained by reverse Northern analysis. In this case, a number of potential false positives generated using reverse Northern analyses, may in reality not be false positives, but instead may represent multiple cDNAs. This problem may be ameliorated by performing single strand conformational polymorphism (SSCP) or reverse Northern analyses using cloned cDNA populations (39,40).

The expression pattern of representative RSDD-derived cDNAs in E11 versus E11-NMT and in a more expanded E11/E11-NMT progression cell culture series is shown in Figs. 3 and 4, respectively. Reverse Northern results correlated well with Northern blots using E11 and

E11-NMT (~80% concordance) or a larger panel of cells
differentially displaying the progression phenotype,
including progression negative, E11, CREF x E11-NMT F1,
CREF X E11-NMT F2, E11 X E11-NMT A6, E11 X E11-NMT 3b,
E11-NMT Aza B1 and E11-NMT Aza C1, and progression
positive E11-NMT, CREF X E11-NMT R1, CREF X E11-NMT R2,
E11 X E11-NMT A6TD, E11 X E11-NMT IIa, E11-ras and
E11-HPV E6/E7.   Sequence analysis of the various
progression upregulated genes (PEGen) and progression
suppressed genes (PSGen) identified both known and
unknown genes (Table 2).   Known PEGen genes included
PEGen 7 (HPV16 E1BP), PEGen 8 (PFK-C), PEGen 21 (FIN 14)
and PEGen 26 (poly ADP-ribose polymerase) and a known
PSGen gene was PSGen 10 (ferritin heavy chain).   Two
PEGen genes out of six were found to be novel (PEGen 14
and PEGen 24) and two PSGen genes out of three were found
to be novel (PSGen 12 and PSGen 13) (Table 2).

-35-

Table 2.   Differentially Expressed cDNA Fragments
           Cloned by RSDD

PSGen 27	Novel	Novel
PSGen 28	Novel	Novel
PSGen 29	Novel	Novel

PEGen 7 is expressed at ~ 5-fold higher levels in E11-NMT than in E11 cells. PEGen 7 is ~90% homologous to 16E1-BP, a cDNA encoding a protein identified using the yeast two-hybrid assay that interacts with human papillomavirus type 16 E1 protein (41). 16E1-BP encodes a 432aa protein of unknown function but does contain an ATPase signature motif (Gly-X_4-Gly consensus ATP binding motif at aa 179 through 186). 16E1-BP appears to be a form of TRIP13, a protein previously shown to bind thyroid hormone receptor in yeast two-hybrid assays. The role of PEGen 7/16E1-BP in the progression phenotype in the E11/E11-NMT progression model is not known. Additional studies are necessary to determine if this gene change is associative or causative of transformation progression.

PEGen 8 is expressed at ~3- to 4- fold higher levels in E11-NMT than in E11 cells. PEGen 8 shows 100% homology to rat phosphofructokinase C (PFK-C) (42). PFK catalyzes the rate-limiting and committed step in glycolysis, the conversion of fructose 6-phosphate to fructose 1,6-biphosphate. Three subunit isozymes of PFK have been identified, that form homo- and heterotetramers with differing catalytic and allosteric properties. PFK-M is

specific for cardiac and skeletal muscle, PFK-L is
expressed in many tissues but is most abundant in the
liver and PFK-C is expressed in several brain regions and
the anterior pituitary but not in liver, skeletal muscle,
5   or several other human tissues. The cDNA of PFK-C
isolated from a rat hypothalamic cDNA library is 2643 bp
and encodes a protein of 765aa (42). In a recent study,
Sanchez-Martinez and Aragon (43) demonstrated that PFK-C
is the predominant form of PFK in ascites tumor cells
10   (obtained from a transplantable mouse carcinoma of
mammary origin), whereas PFK-L is most abundant in the
normal mammary gland. These results suggest the
interesting possibility that PFK-C might contribute to
the malignant nature of specific target cells. The role
15   of PEGen 8/PFK-C in progression in the E11/E11-NMT model
remains to be determined.

PEGen 21 is expressed at ~3- to 4-fold higher levels in
E11-NMT than in E11 cells. PEGen 21 displays ~94%
20   homology with the fibroblast growth factor-4 inducible
gene FIN-14 (44). FIN-14 is a novel cDNA of unknown
function that hybridizes with a 4.5 kb mRNA that is
induced 4-fold in NIH3T3 mouse cells following treatment
with FGF-4. The induction of FIN-14 occurs late (18 hr)
25   after treatment with FGF-4 and does not occur when cells
are treated for 18 hr with FGF-4 in the presence of
cycloheximide (44). These results confirm that FIN-14
encodes a late-inducible gene. Moreover, nuclear run-on
assays document that FIN-14 is trancriptionally activated
30   in NIH3T3 cells following growth factor stimulation.
Tissue distribution studies indicate expression of a
single mRNA species in the kidney with low levels of
expression observed in several other tissues including
testis and thymus. Mouse embryogenesis studies indicate
35   that FIN-14 expression occurs constitutively in mouse
embryos between day 10.5 and 15.5. Unlike NIH3T3, FIN-14
was constitutively expressed in PC12 cells and its level

-38-

did not vary appreciably in response to growth factor stimulation. The role of PEGen 21/FIN-14 in progression in E11/E11-NMT model system is not currently known.

5   The PSGen cDNAs, PSGen-12 and PSGen-13, consist of sequences without homology to those presently reported in various DNA databases. Expression of these cDNAs is ~3- to 4-fold higher in E11 versus E11-NMT cells (Fig. 3). It is not currently known whether these genes simply
10   correlate with or functionally regulate the progression phenotype. The identification of full-length cDNAs for PSGen-12 and PSGen-13 are in progress and once identified experiments can be conducted to directly define the role of these PSGen's in cancer progression.

15
       We presently demonstrate that a modified differential RNA display technique, RSDD, can efficiently identify differentially expressed cDNAs. As predicted, subtractive hybridization prior to differential RNA
20   display greatly reduces band complexity, a problem encountered in standard DDRT-PCR in which RNA samples are directly analyzed without subtraction. Unlike a previous report using subtracted cDNAs processed through successive rounds of PCR (32,45), common bands were
25   eliminated using reciprocally subtracted cDNA libraries that had not been processed using PCR. In addition to subtraction hybridization, the discovery of differentially expressed genes was further streamlined by using reverse Northern analyses with isolated cDNAs.
30   With 3 single anchored oligo dT primers and 18 arbitrary 5' primers, 72 bands were identified that displayed differential expression using reverse Northern analysis. Currently, 40 of these cDNA species have been analyzed by Northern blotting and found to display differential
35   expression in E11 versus E11-NMT cells. Subsequent studies with the majority of these RSDD cDNAs demonstrated coordinated expression with the progression

-39-

phenotype in a large panel of unprogressed and progressed
transformed cells. Current sequence analysis of the
cloned cDNA fragments revealed 9 different genes,
including 4 novel genes not reported in recent DNA
databases. RSDD represents a method of choice either as
a more efficient and less time consuming modification of
the differential RNA display strategy or as a screening
methodology for identifying differentially expressed
genes in reciprocally subtracted cDNA libraries.

Second Series of Experiments

Presently described is a RSDD approach that efficiently
and consistently reduces the complexity of DDRT-PCR and
5   results in the identification and cloning of genes
displaying anticipated differential expression. The model
used for RSDD was an adenovirus-transformed rat embryo
cell line, E11, that acquires an aggressive oncogenic
progression phenotype when injected into athymic nude
10   mice   and   reestablished   in   cell   culture
(E11-NMT)(6,26,27). Injection of E11 cells into nude mice
results in tumors in 100% of animals with a tumor latency
time of approximately 35 to 40 days, whereas E11-NMT
cells form tumors in 100% of nude mice with a tumor
15   latency time of 15 to 20 days (6,26,27). Additionally,
E11 cells form colonies in agar with an efficiency of ~3
%, whereas E11-NMT display an agar cloning efficiency of
>30% (6,26,27). The increased tumorigenicity and enhanced
anchorage independence phenotypes are key indicators of
20   tumor progression in the E11/E11-NMT model system
(6,26,27). RSDD has resulted in the identification and
cloning of genes displaying elevated expression in
progressed tumor cells (progression elevated gene, PEGen)
and suppressed expression in progressed tumor cells
25   (progression suppressed gene, PSGen).

MATERIALS AND METHODS
RNA isolation and cDNA library construction. Total RNA
from E11 and E11-NMT cells was isolated by the
30   guanidinium isothiocyanate/CsCl centrifugation procedure
and poly(A)$^+$ RNA was purified with oligo(dT) cellulose
chromatography(5). Two λ-ZAP cDNA libraries from E11 and
E11-NMT mRNAs were constructed with λ-ZAP cDNA library
kits (Stratagene) following the manufacturer's protocol.
35   Reciprocal subtraction between E11 and E11-NMT libraries
was performed and two subtracted cDNA libraries (E11
minus E11-NMT and E11-NMT minus E11) were constructed as

-48-

described(5,6). Plasmid cDNA libraries from the
subtracted λ-ZAP cDNA libraries were obtained by in vivo
excision   following   the   manufacturer's   protocol
(Stratagene) and the plasmids were isolated with Qiagen

5   columns (Qiagen, Chatsworth, CA.).

      RSDD methodology. The purified plasmids of reciprocally
      subtracted cDNA libraries were directly subjected to
      differential display as in Liang et al. (28) with minor

10   modifications. The plasmids of reciprocally subtracted
      cDNA libraries were PCR-amplified with the combination of
      three single-anchor 3' primers ($T_{13}A$, $T_{13}C$ or $T_{13}G$) and 18
      arbitrary   5'   10-mer   primers   obtained   from   Operon
      Technology Inc. (Alameda, CA. OPA 1-20 except OPA1 and

15   3). The 20 μl PCR reaction consisted of 10 mM Tris-HCl
      (pH 8.4), 50 mM KCl, 1.5 mM $MgCl_2$, 2 μM each dNTP, 0.2 μM
      5' arbitrary primer, 1 μM 3' anchor primer, 50 ng of
      plasmid of a subtracted library, 10 μCi α-^{35}S-dATP (3,000
      Ci/mmol from Amersham) and 1 unit of Taq DNA polymerase

20   (Gibco/BRL). The parameters of PCR were 30 sec at 95°C, 40
      cycles of 30 sec at 95°C, 2 min at 40°C and 30 sec at 72°C
      and additional 5 min. at 72°C. After the cycling, 10 μl of
      95% formamide, 0.05% bromophenol blue and 0.05% xylene
      cyanol were added to each PCR reaction. The mixture was

25   heated at 95°C for 2 min and separated in a 5% denaturing
      DNA sequencing gel maintained at 50°C. PCR reactions of
      plasmids from each subtracted library in a primer set
      were run side by side. Differentially amplified bands
      from plasmids of each subtracted library were marked with

30   18G needle through the film and cut out with a razor. The
      gel slice was put in 100 μl TE (pH 8.0) and incubated at
      4°C overnight. After the incubation, the mixture was
      boiled for 5 min and microcentrifuged for two min. The
      supernatant was collected and stored at -20°C until

35   reamplification. The band extract was reamplified with
      the same cycling parameters in a 50 μl reaction
      consisting of 10 mM Tris-HCl (pH 8.4), 50 mM KCl, 1.5 mM

-49-

MgCl$_2$, 20 μM each dNTP, 0.2 μM 5' arbitrary primer, 1 μM 3' anchor primer, 5μl of band extract and 2.5 units of Taq DNA polymerase (Gibco/BRL).

Reverse Northern Blotting Procedure. Differential expression of the reamplified DNA fragment was scrutinized by reverse Northern and Northern blot analyses. In reverse Northern analysis, after confirmation in a 1% agarose gel, the reamplified DNA fragment (10 μl of PCR reaction) was mixed with 90 μl TE and spotted on a positively charged Nylon membrane (Boehringer Mannheim) with a 96-well vacuum manifold. The membrane was soaked with denaturing and neutralizing solution successively, and the spotted DNA was crosslinked to the membrane with a UV crosslinker (Stratagene). ^{32}P-labeled first strand cDNA was prepared by reverse transcription of total RNA. After heating at 70°C for 10 min and quenching on ice for two min, 0.4 μM each T$_{13}$A, T$_{13}$G and T$_{13}$C and 10 μg total RNA mixture was added with 50 mM Tris-HCl, (pH 8.3), 75 mM KCl, 3 mM MgCl$_2$, 10 mM DTT, 0.5 mM dATP, 0.5 mM dGTP, 0.5 mM dTTP, 0.02 mM dCTP, 0.5 μl RNase inhibitor (Gibco/BRL), 100 μCi dCTP (3,000 Ci/mmol from Amersham) and 200 units Superscript RT II (Gibco/BRL) in a final 25 μl reaction. The reaction mixture was incubated at 42°C for one hour and at 37°C for 30 min after addition of 2 μl of RNase H (10 units, Gibco/BRL). The membrane was hybridized at 42°C overnight in a 50% formamide hybridization solution. The hybridized membrane was washed at room temperature for 15 min with 2X standard saline citrate containing 0.1% SDS twice and at 55°C for at least one hour with 0.1X Standard Saline Citrate containing 0.1% SDS, successively. The membrane was probed with the ^{32}P-labeled cDNA of E11, striped off and probed with ^{32}P-labeled cDNA of E11-NMT. The signal intensity of each spot was normalized against that of glyceraldehyde-3-phosphate dehydrogenase and compared between E11 and E11-NMT. Reamplified DNA

-50-

fragments displaying differential expression levels
≥1.8-fold higher between the two cell types were selected
and analyzed by Northern bloting analysis.

5   **Northern Blotting Analysis.** In Northern blot analysis, 10
µg of total RNA from E11 and E11-NMT cells were run
side-by-side in a 1% agarose gel with formaldehyde and
transferred to a positively charged Nylon membrane.
Reamplification reaction (5 µl) was ^{32}P-labeled with a
10   multiprime labeling kit (Boehringer Mannheim) used to
probe the membrane as described above. DNA fragments
expressed differentially between E11 and E11-NMT in
Northern blot analyses were cloned into the EcoRV site of
the pZEro-2.1 cloning vector (Invitrogene) and sequenced.
15

To confirm differential expression, the cloned cDNA
fragment was released by EcoRI-XhoI, ^{32}P-labeled and used
to probe Northern blots as described above. Samples of
RNAs from various E11 and E11-NMT derivatives displaying
20   either a progressed or suppressed progression phenotype,
based on nude mice tumorigenesis and soft agar cloning
assays were analyzed. These included E11, E11-NMT, CREF
x E11-NMT F1 and F2 somatic cell hybrids (suppressed
progression phenotype), CREF x E11-NMT R1 and R2 somatic
25   cell hybrids (progression phenotype), E11 x E11-NMT A6
somatic cell hybrid (suppressed progression phenotype),
E11 x E11-NMT A6TD tumor-derived somatic cell hybrid
(progression phenotype), E11 x E11-NMT 3b somatic cell
hybrid (suppressed progression phenotype), E11 x E11-NMT
30   IIa (progression phenotype), E11-NMT AZA B1 and C1
5-azacytidine treated E11-NMT clones (suppressed
progression phenotype), E11-Ras R12 clone containing the
Ha-ras oncogene (progression phenotype) and E11-HPV E6/E7
clone containing the human papilloma virus-18 E6 and E7
35   gene region (progression phenotype). Differential
expression of the PEGen and PSGen genes in the various
cell types was confirmed using ^{32}P-labeled probes and

-51-

northern hybridization analysis. After reconfirmation of
differential expression, the plasmids containing the
differentially expressed DNA fragments were sequenced by
the dideoxy sequencing procedure.

5

RESULTS AND DISCUSSION

Subtraction hybridization provides a direct means of
enriching for unique cDNA species and eliminating common
sequences between complex genomes(7,18). DDRT-PCR is a
10   proven methodology for the rapid identification and
cloning of differentially expressed sequences between
cell types (1,2,28). In principle, subtraction
hybridization combined with DDRT-PCR should reduce band
complexity which often obscures the identification of
15   differentially expressed genes and generates false
positive signals (21,29). RSDD has been used to analyze
genes differentially expressed during transformation
progression (Fig. 28). Differential RNA display was
directly performed with reciprocally subtracted cDNA
20   plasmid libraries (E11 minus E11-NMT and E11-NMT minus
E11) that had not been subjected to PCR. Three single
anchored oligo dT 3' primers were used for subsequent
amplification prior to display. To further streamline the
DDRT-PCR procedure, reamplified cDNAs identified using
25   RSDD were analyzed using the reverse Northern blotting
procedure (30,31). cDNAs displaying differential
expression by reverse Northern blotting were subsequently
confirmed for true differential expression by Northern
analysis.

30

The differential RNA display pattern of E11 and E11-NMT
cells using standard differential RNA display (DDRT-PCR)
and RSDD is shown in Fig. 1 (Left Panel). The
differential RNA display pattern of RSDD is much less
35   complex than that of DDRT-PCR. These experiments
demonstrate that subtractive hybridization prior to
differential RNA display is effective in simplifying

-52-

display patterns permitting the efficient identification of differentially expressed cDNAs. Since RSDD significantly reduced the number of bands displayed, single anchor oligo dT primers, that can increase band numbers, were successfully used in subsequent applications of the RSDD approach (Fig. 1; Right Panel). Using RSDD, 234 differentially displayed cDNAs in the E11/E11-NMT tumor progression model system were isolated. Hakvoort et al.(25) used a reciprocal subtraction approach to analyze gene expression changes resulting during liver regeneration following 70% hepatectomy, i.e., normal liver subtracted from partially hepatectomized regenerating liver and vice versa. Although some bands displayed apparent enrichment, the complexity of the display pattern did not show appreciable simplification. In contrast, RSDD results in a clearer delineation and simplification of differentially expressed amplified bands (Figs. 1). Although conceptually similar, RSDD is significantly more effective than the subtraction plus DDRT-PCR approach described by Hakvoort et al. (25) The reasons for the improved efficiency of RSDD versus the Hakvoort et al. (25) approach are not known. One possibility is that the differences between the experimental approaches may reflect the subtraction hybridization strategies employed. The approach of Hakvoort et al. (25) is based on the subtraction procedure described by Wang and Brown (32). This approach uses multiple rounds of PCR-amplification prior to each round of subtractive hybridization. In contrast, RSDD involves a single round of reciprocal subtraction without intermediate amplification(5,6). In this respect, the complicated display pattern observed by Hakvoort et al. (25) even after three or four rounds of subtraction might result from reduced subtraction efficiency, PCR artifacts or a combination of these problems. Increasing the number of reactions by using two-base pair anchored oligo dT

-53-

primers did not reduce the complexity of displayed bands
(25). In these contexts, a critical component for the
successful use of RSDD involves the use of an appropriate
subtraction hybridization protocol, which can efficiently
5   reduce cDNA complexity and generate stable populations of
cDNAs for analysis.

Previous studies demonstrate that different gene cloning
strategies, including DDRT-PCR, subtraction hybridization
10   and electronic display, identify distinct subsets of
differentially expressed genes (18). These results
suggest that a single approach for gene identification
may not identify the complete spectrum of differentially
expressed genes. Similarly, RSDD and DDRT-PCR do not
15   resolve the same differentially expressed bands (Fig. 1).
Unique bands identified in DDRT-PCR that were
differentially expressed when analyzed by Northern
blotting were not the same as those found using RSDD and
vise versa (data not shown). These results are not
20   surprising, since, as indicated above, subtraction
hybridization and differential RNA display identified
distinct differentially expressed genes (18). Apparently,
specific differentially expressed genes are lost during
subtraction hybridization and differential RNA display of
25   subtracted cDNAs. On the basis of these considerations,
it will be essential to use multiple gene discovery
approaches to identify and clone the complete spectrum of
differentially expressed genes.

30   DDRT-PCR can generate large numbers of differentially
displayed bands making subsequent analysis both labor
intensive and a daunting challenge. In order to reduce
these limitations of DDRT-PCR, RSDD has been used in
combination with reverse Northern analyses of isolated
35   cDNAs. Gel extracted cDNA fragments were reamplified,
dot-blotted on Nylon membranes and successively probed
with reverse transcribed ^{32}P-cDNA from E11 or E11-NMT RNAs

-54-

(Fig. 2). Signals were detected in 181 reamplified bands
out of 234 (77%).

The signal intensities of the various cDNAs in reverse
5   Northern analysis were quantified and normalized against
that of GAPDH, which remained unchanged in E11 and
E11-NMT cells. Progression elevated gene-3 (PEG-3)(6) was
used as an additional control, to verify increased
expression in E11-NMT versus E11 cells. In the reverse
10 Northern analyses, PEG-3 levels were 4-fold higher in
E11-NMT than in E11 cells, which coincided with Northern
blotting results, thereby demonstrating the concordance
of reverse Northern and Northern assays. A $\geq$ 1.8-fold
differential cut-off (after normalization for GAPDH
15 expression) was used to identify and isolate cDNA bands
displaying modified expression in E11 versus E11-NMT
cells. This resulted in the identification of 7 cDNAs
with higher expression in E11 versus E11-NMT cells and 65
cDNAs with elevated expression in E11-NMT versus E11
20 cells. These results suggest that tumor progression in
E11-NMT cells correlates with increased expression of a
large number of genes, whereas only a smaller subset of
genes display decreased expression.

25 A problem frequently encountered in DDRT-PCR, that is
reduced but still can occur in RSDD, is the isolation of
multiple cDNA species from what appears to be a single
amplified band. When this occurs, these multiple species
can produce spurious results when analyzed by reverse
30 Northern analyses. For example, if two distinct species
are isolated, one displaying modified expression and a
second not displaying modified expression, an accurate
estimate of differential expression will not be obtained
by reverse Northern analysis. In this case, a number of
35 potential false positives generated using reverse
Northern analyses, may in reality not be false positives,
but instead may represent multiple cDNAs. By performing

-55-

single strand conformational polymorphism (SSCP) or
reverse Northern analyses using cloned cDNA populations
(33,34) this problem can be ameliorated.

5   The expression pattern of representative RSDD-derived
cDNAs in E11 versus E11-NMT and in a more expanded
E11/E11-NMT progression cell culture series is shown in
Figs. 29 and 30, respectively. Reverse Northern results
correlated well with Northern blots using E11 and E11-NMT
10   (~75% concordance) or a larger panel of cells
differentially displaying the progression phenotype,
including progression negative E11, CREF x E11-NMT F1 and
F2, E11 x E11-NMT A6, E11 x E11-NMT 3b, E11-NMT Aza B1
and Aza C1 cells, and progression positive E11-NMT, CREF
15   x E11-NMT R1 and R2, E11 x E11-NMT A6TD, E11 x E11-NMT
IIa, E11-Ras R12 and E11-HPV E6/E7 cells. Sequence
analysis of the various PEGen cDNAs identified both
unknown and known genes (Table 3). Five of 10 PEGen cDNAs
(50%) were classified as novel sequences since no matches
20   were found in current DNA databases. Novel PEGen cDNAs
include, PEGen 13, 14, 24, 28 and 32. Known PEGen genes
included PEGen 7 (human papilloma virus-16 early region
1 binding protein; HPV16 E1BP), PEGen 8
(phosphofructokinase kinase C; PFK-C), PEGen 21 (a
25   fibroblast growth factor-4 inducible gene; FIN 14), PEGen
26 (poly ADP-ribose polymerase) and PEGen 30 (rat esp1
homology). In the case of the PSGen cDNAs, six of six
(100%) were novel, including PSGen 12, 13, 26, 27, 28 and
29 (Table 3).

30

35

-56-

Table 3. PEGen and PSGen genes isolated using RSDD

Nomenclature[a]	Identity[b]	H o m o l o g y (%)[c]
PEGen 7	Human HPV16 E1BP	90

PEGen 21	Murine FIN 14	94
PEGen 24	Unknown	Novel
PEGen 26	Rat poly ADP-ribose	
	polymerase 100	
PEGen 28	Unknown	Novel
PEGen 30	Rat esp1	98
PEGen 32	Novel	Novel
PSGen 12	Unknown	Novel
PSGen 13	Unknown	Novel
PSGen 26	Unknown	Novel
PSGen 27	Unknown	Novel
PSGen 28	Unknown	Novel
PSGen 29	Unknown	Novel

[a]PEGen are progression elevated genes that display elevated expression in E11-NMT versus E11 cells. PSGen are progression suppressed genes that display elevated expression in E11 versus E11-NMT cells.
[b]Sequences have compared with reported genes in various DNA data bases (including GenBank and EMBL) and identification with known genes are indicated. Genes without homology to currently reported genes are indicated as unknown.
[c]percentage homology with known sequences, either human, rat or mouse is indicated.
Where no homology exsists the cDNA is considered novel.

PEGen 7 is expressed at ~ 4-fold higher levels in E11-NMT
than in E11 cells. PEGen 7 is ~98% homologous to 16E1-BP,
a cDNA encoding a protein identified using the yeast
two-hybrid assay that interacts with human papillomavirus
type 16 E1 protein (35). 16E1-BP encodes a 432aa protein
of unknown function but does contain an ATPase signature
motif (Gly-X4-Gly consensus ATP binding motif at aa 179
through 186). 16E1-BP appears to be a form of TRIP13, a
protein previously shown to bind thyroid hormone receptor
in yeast two-hybrid assays. The role of PEGen 7/16E1-BP
in the progression phenotype in the E11/E11-NMT
progression model is not known. Additional studies are
necessary to determine if this gene change is associative
or causative of transformation progression.

PEGen 8 is expressed at ~3- to 4- fold higher levels in
E11-NMT than in E11 cells. PEGen 8 shows 100% homology to
rat phosphofructokinase C (PFK-C)(36). PFK catalyzes the
rate-limiting and committed step in glycolysis, the
conversion of fructose 6-phosphate to fructose
1,6-biphosphate. Three subunit isozymes of PFK have been
identified, that form homo- and heterotetramers with
differing catalytic and allosteric properties. PFK-M is
specific for cardiac and skeletal muscle, PFK-L is
expressed in many tissues but is most abundant in the
liver and PFK-C is expressed in several brain regions and
the anterior pituitary but not in liver, skeletal muscle,
or several other human tissues. The cDNA of PFK-C
isolated from a rat hypothalamic cDNA library is 2643 bp
and encodes a protein of 765aa (-36). In a recent study
Sanchez-Martinez and Aragon (37), demonstrated that PFK-C
is the predominant form of PFK in ascites tumor cells
(obtained from a transplantable mouse carcinoma of
mammary origin), whereas PFK-L is most abundant in the
normal mammary gland. These results suggest the
interesting possibility that PFK-C might contribute to
the malignant nature of specific target cells. The role

-58-

presently reported of PEGen 8/PFK-C in progression in the E11/E11-NMT model remains to be determined.

PEGen 21 is expressed at ~3- to 4-fold higher levels in E11-NMT than in E11 cells. PEGen 21 displays ~98% homology with the fibroblast growth factor-4 inducible gene FIN-14 (38). FIN-14 is a novel cDNA of unknown function that hybridizes with a 4.5 kb mRNA that is induced 4-fold in NIH 3T3 mouse cells following treatment with FGF-4. The induction of FIN-14 occurs late (18 hr) after treatment with FGF-4 and does not occur when cells are treated for 18 hr with FGF-4 in the presence of cycloheximide (38). These results confirm that FIN-14 encodes a late-inducible gene. Moreover, nuclear run-on assays document that FIN-14 is transcriptionally activated in NIH 3T3 cells following growth factor stimulation. Tissue distribution studies indicate expression of a single mRNA species in the kidney with low levels of expression observed in several other tissues including testis and thymus. Mouse embryogenesis studies indicate that FIN-14 expression occurs constitutively in mouse embryos between day 10.5 and 15.5. Unlike NIH 3T3, FIN-14 was constitutively expressed in PC12 cells and its level did not vary appreciably in response to growth factor stimulation. The role of PEGen 21/FIN-14 in progression in E11/E11-NMT model system is not currently known.

PEGen 26 is expressed at ~3- to 4-fold higher levels in E11-NMT than in E11 cells. This cDNA is identical to rat poly(ADP-ribose) polymerase (PARP)(39). PARP contributes to the ability of eukaryotic cells to contend with both environmental and endogenous genotoxic agents (40). PARP is a nuclear enzyme that binds to DNA breaks and then catalyzes the covalent modification of acceptor proteins with poly(ADP-ribose) (39,40). PARP activity contributes to the recovery of proliferating cells from DNA damage

and to the maintenance of genomic stability, which may be regulated by effects on chromatin structure, DNA base-excision repair and cell cycle regulation (39,40). The role of PEGen 26/PARP in mediating the progression phenotype is not currently known. However, since cancer is a progressive disease characterized by the accumulation of genetic alterations in the evolving tumor (6), it is tempting to speculate that overexpression of PEGen 26/PARP in E11-NMT may facilitate the ability of these aggressive cancer cells to maintain genomic stability during cancer progression. In this context, PEGen 26/PARP may be an integral component of progression. This hypothesis is readily testable. PEGen 30 is expressed at 2- to 3-fold higher levels in E11-NMT than in E11 cells. This cDNA displays ~98.5% homology to rat esp1 (41). Rat esp1 encodes a 24-kDa nuclear protein which is the rat homologue of Drosophila Enhancer of split., a gene involved in ventral ectodermal development in Drosophila (41). PEGen 30 appears to be a homologue of esp1, since the message detected in E11 and E11-NMT cells (~4 kb) is larger in size than the reported esp1 transcript (1.3 kb)(41). The role of PEGen 30/esp1 in tumor progression in E11/E11-NMT model system remains to be determined.

The PSGen cDNAs, 12, 13, 26, 27, 28 and 29, consist of sequences without homology to those in various DNA data bases. Expression of PSGen 12 and PSGen 13 cDNAs is ~3- to 4-fold higher in E11 versus E11-NMT cells (Fig. 29). It is not currently known whether these genes simply correlate with or functionally regulate the progression phenotype. The identification of full-length cDNAs for PSGen-12 and PSGen-13, as well as the other novel PSGen and PEGen cDNAs, are in progress and once isolated experiments can be conducted to directly define the role of these progression-related genes in cancer progression.

-60-

Presently demonstrated is a modified gene-identification and gene-cloning technique, RSDD, that can efficiently identify differentially expressed cDNAs. As predicted, subtractive hybridization prior to differential RNA display greatly reduces band complexity, a problem encountered in standard DDRT-PCR in which RNA samples are directly analyzed without subtraction. Unlike a previous report using subtracted cDNAs processed through successive rounds of PCR (25,42), common bands were eliminated using reciprocally subtracted cDNA libraries that had not been processed using PCR. In addition to subtraction hybridization, the discovery of differentially expressed genes was further streamlined by using reverse Northern analyses with isolated cDNAs. With 3 single anchored oligo dT primers and 18 arbitrary 5' primers, 72 bands were identified that displayed differential expression using reverse Northern analysis. Currently, 38 cDNA species have been analyzed by Northern blotting and 31 (~82%) displayed differential expression in E11 versus E11-NMT cells. Sequence analysis of the cloned cDNA fragments revealed 16 different genes, including 11 novel genes not reported in recent DNA databases. RSDD represents a method of choice either as a more efficient and less time consuming modification of the differential RNA display strategy or as a screening methodology for identifying differentially expressed genes in reciprocally subtracted cDNA libraries. Moreover, the ability of RSDD to identify differentially expressed genes that are dissimilar to those recognized using standard DDRT-PCR or subtraction hybridization indicates that this approach will be a valuable adjunct in cloning the complete repertoire of differentially expressed gene changes occurring between complex genomes.

-66-

What is claimed is:

1.   A method for identifying differentially expressed
     nucleic acids between two samples, comprising:
     a.   selecting a first and second nucleic acid
          sample, wherein the nucleic acid samples
          contain a repertoire of nucleic acids;
     b.   performing reciprocal subtraction between
          the nucleic acid samples to produce two
          subtracted nucleic acid samples;
     c.   amplifying the two subtracted nucleic
          acid samples; and
     d.   comparing the two subtracted nucleic acid
          samples to identify differentially
          expressed nucleic acids.

2.   A method for identifying differentially expressed
     nucleic acids between two samples, comprising:
     a.   selecting a first and second nucleic acid
          sample, wherein the nucleic acid samples
          contain a repertoire of nucleic acids;
     b.   amplifying the two nucleic acid samples;
     c.   performing reciprocal subtraction between
          the amplified nucleic acid samples to
          produce two subtracted nucleic acid
          samples; and
     d.   comparing the two subtracted nucleic acid
          samples to identify differentially
          expressed nucleic acids.

3.   The method of claim 2, wherein the two subtracted
     nucleic acid samples from step c are amplified prior
     to the comparing of step d.

4.   The method of claim 1 or 2, wherein the each of the
     nucleic acid samples comprises a library of nucleic
     acids.

-67-

5. The method of claim 1 or 2, wherein the nucleic acid samples are mRNA or cDNA derived from mRNA.

6. The method of claim 1 or 2, wherein the nucleic acid samples are obtained from total RNA from E11 and E11-NMT cells.

7. The method of claim 1 or 2, wherein the first and second nucleic acid samples are obtained from cells that differ in their exposure to external factors or in their gene expression.

8. The method of claim 1 or 2, wherein the first and second nucleic acid samples are obtained from cells in different developmental stages.

9. The method of claim 1 or 2, wherein the amplifying of step (d) comprises PCR amplification.

10. The method of claim 9, wherein the PCR amplification uses a set of random primers.

11. The method of claim 9, wherein the 3' primer used in the PCR amplification is a single anchor oligo dT 3' primer.

12. The method of claim 9, wherein the 5' primer is an arbitrary primer.

13. The method of claim 1 or 2, wherein the comparing of step (e) comprises using a gel to separate the nucleic acids from both of the libraries.

14. The method of claim 1 or 2, further comprising PCR amplifying the first and second nucleic acid samples.

15. The method of claim 1 or 2, further comprising reamplifying differentially expressed nucleic acids.

16. The method of claim 1 or 2, wherein the comparing of step (e) comprises comparing the quantities of the two amplified differentially expressed nucleic acids.

17. The method of claim 1 or 2, wherein differences in the quantities of nucleic acid between the two subtracted libraries are electronically quantified.

18. The method of claim 1 or 2, wherein the libraries of step (b) are constructed with λ-ZAP cDNA library kits.

19. The isolated nucleic acid identified by the method of claim 1 or 2, wherein the nucleic acid was not previously known.

20. The isolated nucleic acid of claim 19, wherein the isolated nucleic acid is the nucleic acid designated PSGen 12.

21. The isolated nucleic acid of claim 19, wherein the isolated nucleic acid is the nucleic acid designated PSGen 13.

22. The isolated nucleic acid of claim 19, wherein the isolated nucleic acid is the nucleic acid designated PSGen 23.

23. The isolated nucleic acid of claim 19, wherein the isolated nucleic acid is the nucleic acid designated PSGen 24.

24. The isolated nucleic acid of claim 19, wherein the

-69-

isolated nucleic acid is the nucleic acid designated
PSGen 25.

25.   The isolated nucleic acid of claim 19, wherein the
       isolated nucleic acid is the nucleic acid designated
       PSGen 26.

26.   The isolated nucleic acid of claim 19, wherein the
       isolated nucleic acid is the nucleic acid designated
       PSGen 27.

27.   The isolated nucleic acid of claim 19, wherein the
       isolated nucleic acid is the nucleic acid designated
       PSGen 28.

28.   The isolated nucleic acid of claim 19, wherein the
       isolated nucleic acid is the nucleic acid designated
       PSGen 29.

29.   The isolated nucleic acid of claim 19, wherein the
       isolated nucleic acid is the nucleic acid designated
       PEGen 13.

30.   The isolated nucleic acid of claim 19, wherein the
       isolated nucleic acid is the nucleic acid designated
       PEGen 14.

31.   The isolated nucleic acid of claim 19, wherein the
       isolated nucleic acid is the nucleic acid designated
       PEGen 15.

32.   The isolated nucleic acid of claim 19, wherein the
       isolated nucleic acid is the nucleic acid designated
       PEGen 24.

33.   The isolated nucleic acid of claim 19, wherein the
       isolated nucleic acid is the nucleic acid designated

PEGen 28.

34.   The isolated nucleic acid of claim 19, wherein the
       isolated nucleic acid is the nucleic acid designated
5   PEGen 32.

35.   The isolated nucleic acid of claim 19, wherein the
       isolated nucleic acid is the nucleic acid designated
       PEGen 42.
10
36.   The isolated nucleic acid of claim 19, wherein the
       isolated nucleic acid is the nucleic acid designated
       PEGen 43.

15 37.   The isolated nucleic acid of claim 19, wherein the
           isolated nucleic acid is the nucleic acid designated
           PEGen 44.

38.   The isolated nucleic acid of claim 19, wherein the
20   isolated nucleic acid is the nucleic acid designated
       PEGen 48.

39.   The isolated nucleic acid molecule of claim 19 which
       comprises:
25   (a)   one of the nucleic acid sequences as set forth
              in Figure 35;

       (b)   a sequence being degenerated to a sequence of
              (a) as a result of the genetic code;
30
       (c)   a sequence encoding one of the amino acid
              sequences as set forth in Figure 35.

       (d)   a sequence of at least 12 nucleotides capable
35   of specifically hybridizing to the sequence of
              (a), (b) or (c)

-71-

40. A purified polypeptide comprising one of the amino acid sequence as set forth in Figure 35.

SEQUENCE LISTING

(1) GENERAL INFORMATION:

   (i) APPLICANT: The Trustees of Columbia University in the City of New York

   (ii) TITLE OF INVENTION: RECIPROCAL SUBTRACTION DIFFERENTIAL
        DISPLAY

   (iii) NUMBER OF SEQUENCES: 24

   (iv) CORRESPONDENCE ADDRESS:
        (A) ADDRESSEE: Cooper & Dunham LLP
        (B) STREET: 1185 Avenue of the Americas
        (C) CITY: New York
        (D) STATE: New York
        (E) COUNTRY: USA
        (F) ZIP: 10036

   (v) COMPUTER READABLE FORM:
        (A) MEDIUM TYPE: Floppy disk
        (B) COMPUTER: IBM PC compatible
        (C) OPERATING SYSTEM: PC-DOS/MS-DOS
        (D) SOFTWARE: PatentIn Release #1.0, Version #1.30

   (vi) CURRENT APPLICATION DATA:
        (A) APPLICATION NUMBER:
        (B) FILING DATE:
        (C) CLASSIFICATION:

   (viii) ATTORNEY/AGENT INFORMATION:
        (A) NAME: White, John P.
        (B) REGISTRATION NUMBER: 28,678
        (C) REFERENCE/DOCKET NUMBER: 55551-C-PCT/JPW/AKC

   (ix) TELECOMMUNICATION INFORMATION:
        (A) TELEPHONE: (212) 278-0400
        (B) TELEFAX: (212) 391-0525

(2) INFORMATION FOR SEQ ID NO:1:

   (i) SEQUENCE CHARACTERISTICS:
        (A) LENGTH: 371 base pairs
        (B) TYPE: nucleic acid
        (C) STRANDEDNESS: not relevant
        (D) TOPOLOGY: linear

# INTERNATIONAL SEARCH REPORT

## A. CLASSIFICATION OF SUBJECT MATTER

IPC(6)    :C12P 21/02; C12Q 1/68; C12N 15/11
US CL    : 530/350; 536/23.1; 435/6
According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. :    530/350; 536/23.1; 435/6

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

NONE

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS, MEDLINE

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

| Category* | Citation of document, with indication, where appropriate, of the relevant passages | Relevant to claim No. |
|---|---|---|
| X | US 4,981,783 A (AUGENLICHT) 01 January 1991, col. 2, lines 40-64. | 19 |
| A | US 5,599,672 A (LIANG et al.) 04 February 1997, see entire document. | 1-40 |

☐ Further documents are listed in the continuation of Box C.  ☐ See patent family annex.

| | |
|---|---|
| *       Special categories of cited documents: | "T"    later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention |
| "A"    document defining the general state of the art which is not considered to be of particular relevance | "X"    document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone |
| "E"    earlier document published on or after the international filing date | |
| "L"    document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified) | "Y"    document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art |
| "O"    document referring to an oral disclosure, use, exhibition or other means | "&"    document member of the same patent family |
| "P"    document published prior to the international filing date but later than the priority date claimed | |

| Date of the actual completion of the international search | Date of mailing of the international search report |
|---|---|

Form PCT/ISA/210 (second sheet)(July 1992)*

# INTERNATIONAL SEARCH REPORT

**Box I   Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)**

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
   because they relate to subject matter not required to be searched by this Authority, namely:

2. ☒ Claims Nos.: 20-40
   because they relate to parts of the international application that do not comply with the prescribed requirements to such
   an extent that no meaningful international search can be carried out, specifically:

   The Computer Readable Form (CRF) of the Sequence Listing as filed does not comply with 37 CFR § 1.821-1.824.
   A; such, claims 20-40 could only be searched in part, by word searching.

3. ☐ Claims Nos.:
   because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

**Box II   Observations where unity of invention is lacking (Continuation of item 2 of first sheet)**

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable
   claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment
   of any additional fee.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers
   only those claims for which fees were paid, specifically claims Nos.:

4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is
   restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

**Remark on Protest**     ☐ The additional search fees were accompanied by the applicant's protest.

☐ No protest accompanied the payment of additional search fees.

Form PCT/ISA/210 (continuation of first sheet(1))(July 1992)*
